Abstract

We study the simultaneous zeros of a random family of $d$ polynomials in $d$ variables over the $p$-adic numbers. For a family of natural models, we obtain an explicit constant for the expected number of zeros that lie in the $d$-fold Cartesian product of the $p$-adic integers. Considering models in which the maximum degree that each variable appears is $N$, this expected value is

$$p^{d\lfloor \log_p N \rfloor}\left(1 + p^{-1} + p^{-2} + \cdots + p^{-d}\right)^{-1}$$

for the simplest such model.

1 Introduction

Various questions regarding the distribution of the number of real roots of a random polynomial were considered in [LO38, LO39, LO43] and were taken up in [Kac43b, Kac43a, Kac49], where the main result is that the expected number of roots of a degree $n$ polynomial with independent standard Gaussian coefficients is asymptotically equivalent to $\frac{2}{\pi} \log n$ for large $n$. There has since been a huge amount of work on various aspects of the distribution of the roots of random polynomials and systems of random polynomials for a wide range of models with coefficients that are possibly dependent and have distributions other than Gaussian. It is impossible to survey this work adequately, but some of the more commonly cited early papers are [LS68a, LS68b, IM71a, IM71b]. Reviews of the literature can be found in [BRS86, EK95, EK96, Far98].

1SUPPORTED IN PART BY NSF GRANT DMS-0405778. PART OF THE RESEARCH WAS CONDUCTED DURING A VISIT TO THE AMERICAN INSTITUTE OF MATHEMATICS FOR A WORKSHOP ON RANDOM ANALYTIC FUNCTIONS.
In this paper we study the roots of random polynomials over a field other than the real or complex numbers, the field of \( p \)-adic numbers for some prime \( p \). Like the reals, the \( p \)-adics arise as a completion of the rationals with respect to certain metric – see below. They are the prototypical local fields (that is, non-discrete, locally compact topological fields) and any local field with characteristic zero is a finite algebraic extension of the \( p \)-adic numbers (the local fields with non-zero characteristic are finite algebraic extensions of the \( p \)-series field of Laurent series over the finite field with \( p \) elements).

In order to describe our results we need to give a little background. For a fuller treatment, we refer the reader to [Sch84] for an excellent introduction to local fields and analysis on them.

We begin by defining the \( p \)-adic numbers. Fix a positive prime \( p \). We can write any non-zero rational number \( r \in \mathbb{Q}\setminus\{0\} \) uniquely as \( r = p^s(a/b) \) where \( a \) and \( b \) are not divisible by \( p \). Set \( |r| = p^{-s} \). If we set \(|0| = 0\), then the map \(|\cdot|\) has the properties:

\[
\begin{align*}
|x| = 0 &\iff x = 0, \\
|xy| &= |x||y|, \\
|x + y| &\leq |x| \vee |y|.
\end{align*}
\]

(1)

The map \((x, y) \mapsto |x - y|\) defines a metric on \( \mathbb{Q} \), and we denote the completion of \( \mathbb{Q} \) in this metric by \( \mathbb{Q}_p \). The field operations on \( \mathbb{Q} \) extend continuously to make \( \mathbb{Q}_p \), a topological field called the \( p \)-adic numbers. The map \(|\cdot|\) also extends continuously and the extension has properties (1). The closed unit ball around 0, \( \mathbb{Z}_p := \{x \in \mathbb{Q}_p : |x| \leq 1\} \), is the closure in \( \mathbb{Q}_p \) of the integers \( \mathbb{Z} \), and is thus a ring (this is also apparent from (1)), called the \( p \)-adic integers. As \( \mathbb{Z}_p = \{x \in \mathbb{Q}_p : |x| < p\} \), the set \( \mathbb{Z}_p \) is also open. Any other ball around 0 is of the form \( \{x \in \mathbb{Q}_p : |x| \leq p^{-k}\} = p^k \mathbb{Z}_p \) for some integer \( k \). Such a ball is the closure of the rational numbers divisible by \( p^k \), and is thus a \( \mathbb{Z}_p \)-sub-module (this is again also apparent from (1)). In particular, such a ball is an additive subgroup of \( \mathbb{Q}_p \). Arbitrary balls are translates (= cosets) of these closed and open subgroups. In particular, the topology of \( \mathbb{Q}_p \) has a base of closed and open sets, and hence \( \mathbb{Q}_p \) is totally disconnected. Further, each of these balls is compact, and hence \( \mathbb{Q}_p \) is also locally compact.

There is a unique Borel measure \( \lambda \) on \( \mathbb{Q}_p \) for which

\[
\begin{align*}
\lambda(x + A) &= \lambda(A), \quad x \in \mathbb{Q}_p, \\
\lambda(xA) &= |x|\lambda(A), \quad x \in \mathbb{Q}_p, \\
\lambda(\mathbb{Z}_p) &= 1.
\end{align*}
\]

The measure \( \lambda \) is just suitably normalized Haar measure on the additive group of \( \mathbb{Q}_p \). The restriction of \( \lambda \) to \( \mathbb{Z}_p \) is the weak limit as \( n \to \infty \) of the sequence of probability measures that at the \( n \)-th stage assigns mass \( p^{-n} \) to each of the points \( \{0, 1, \ldots, p^n - 1\} \).

There is a substantial literature on probability on the \( p \)-adics and other local fields. Two notable early papers are [Mad85] and [Mad90]. We have shown in a sequence papers [Eva89] that the natural analogues on \( \mathbb{Q}_p \) of the centered Gaussian measures on \( \mathbb{R} \) are the normalized restrictions of \( \lambda \) to the compact \( \mathbb{Z}_p \)-sub-modules \( p^k \mathbb{Z}_p \) and the point mass at 0. More generally, the natural counterparts of centered Gaussian measures on \( \mathbb{Q}_p \) are normalized Haar measures on compact \( \mathbb{Z}_p \)-sub-modules. We call such probability measures \( \mathbb{Q}_p \)-Gaussian and say that a random variable distributed according to
normalized Haar measure on $\mathbb{Z}_p^d$ is standard $\mathbb{Q}_p$-Gaussian. There are also numerous papers
Markov processes taking values in local fields, for example [AK91, AK94, AKZ99, AK00, AZ00a, AZ01, AZ02, KZ04, SJZ05]. There are also extensive surveys of the literature in the
books [Khr97, Koc01, KN04].

If we equip the space of continuous functions $C(\mathbb{Z}_p^d, \mathbb{Q}_p)$ with the map $f \mapsto \|f\| := \sup\{|f(t)| : t \in \mathbb{Z}_p^d\}$, then $\| \cdot \|$ is a $p$-adic norm in the sense that

\[ \|f\| = 0 \iff f = 0, \]
\[ \|af\| = |a|\|f\|, \quad a \in \mathbb{Q}_p, \quad f \in C(\mathbb{Z}_p^d, \mathbb{Q}_p), \]
\[ \|f + g\| \leq \|f\| \lor \|g\|. \]

Moreover, $C(\mathbb{Z}_p^d, \mathbb{Q}_p)$ is a $p$-adic Banach space in the sense that it is complete with respect to
the metric $(f, g) \mapsto \|f - g\|$.

There is a natural notion of orthogonality on the space $C(\mathbb{Z}_p^d, \mathbb{Q}_p)$. A collection $\{f_0, f_1, \ldots\}$ is orthogonal if $\|\sum_{k=0}^n a_k f_k\| = \sqrt{\sum_{k=0}^n |a_k| \|f_k\|}$ for any $n$ and any $a_k \in \mathbb{Q}_p$. At first glance, this
looks completely unlike the notion of orthogonality one is familiar with in real and complex
Hilbert spaces, but it can be seen from [Sch84] that there are actually close parallels. It is ap-
parent from [Sch84] that the sequence of functions $\{t \mapsto (t^i)_{k=0}^\infty\}$, where $(t^i) := \frac{t^{(i-1)} - t^{(i+1)}}{k!}$
(the Mahler basis) is a very natural orthonormal basis for $C(\mathbb{Z}_p^d, \mathbb{Q}_p)$ (that is, it is orthogonal
and each element has unit norm). It is not hard to see that the functions

\[ (t_1, t_2, \ldots, t_d) \mapsto \left( \frac{t_1}{k_1}, \frac{t_2}{k_2}, \ldots, \frac{t_d}{k_d} \right), \quad 0 \leq k_1, k_2, \ldots, k_d < \infty, \]

are an orthonormal basis for $C(\mathbb{Z}_p^d, \mathbb{Q}_p)$.

Putting all of these ingredients together, we see that a natural model for a random system of$d$ independent identically distributed $\mathbb{Q}_p$-valued polynomials in $d$ variables lying in $\mathbb{Z}_p$ is the system

\[ F_i(t_1, t_2, \ldots, t_d) := \sum_k a_k Z_i, k \left( \frac{t_1}{k_1}, \frac{t_2}{k_2}, \ldots, \frac{t_d}{k_d} \right), \quad 1 \leq i \leq d, \]

where the sum is over multi-indices $k = (k_1, k_2, \ldots, k_d)$, for each $i$ the constants $a_k \in \mathbb{Q}_p$
are zero for all but finitely many $k$, and the $\mathbb{Q}_p$-valued random variables are independent and standard $\mathbb{Q}_p$-Gaussian distributed.

**Assumption 1.1.** Assume that $a_0 \neq 0$ and $a_{e_j} \neq 0$ for $1 \leq j \leq d$, where $e_1 := (1, 0, 0, \ldots, 0)$,
$e_2 := (0, 1, 0, \ldots, 0)$, and so on. By re-scaling, we can assume without loss of generality that $a_0 = 1$ for $1 \leq i \leq d$. We will also suppose that $|a_k| \geq |a_\ell|$ when $k \leq \ell$ in the usual partial
order on multi-indices (that is, if $k = (k_1, k_2, \ldots, k_d)$ and $\ell = (\ell_1, \ell_2, \ldots, \ell_d)$, then $k_j \leq \ell_j$ for
$1 \leq i \leq d$). It follows from the orthonormality of the products of Mahler basis elements that
each $(F_1, F_2, \ldots, F_d)$ maps $\mathbb{Z}_p^d$ into $\mathbb{Z}_p^d$.

**Theorem 1.2.** Suppose that Assumption **1.1** holds. For $(x_1, x_2, \ldots, x_d) \in \mathbb{Z}_p^d$, the expected
number of points in the set

\[ \{ (t_1, t_2, \ldots, t_d) \in \mathbb{Z}_p^d : F_i(t_1, t_2, \ldots, t_d) = x_i, \ 1 \leq i \leq d \} \]
is

\[ \left[ \prod_{j=1}^d \left( \sum_{h=1}^\infty a_{he_j} \frac{1}{h} \right) \right] (1 + p^{-1} + p^{-2} + \cdots + p^{-d})^{-1}. \]
Following some preliminaries in Section 2 we give the proof in Section 3. However, we provide a heuristic argument now as motivation for the development we need to do in Section 2. Because we are arguing heuristically, we do not justify various interchanges of limits, sums and expectations.

Suppose first that \( d = 1 \) and \( x = 0 \). Write \( F = \sum_k a_k Z_k(\lambda) \) for \( F_1 \). Let \( B_{n,0}, B_{n,1}, \ldots, B_{n,p^{n-1}} \) be a list of the balls of radius \( p^{-n} \) in \( \mathbb{Z}_p \), numbered so that \( 0 \in B_{n,0} \). Let \( I_{i,j}^{m,n} \) be the indicator of the event that the graph of \( F \) intersects \( B_{m,i} \times B_{n,j} \). The number of zeros of \( F \), \( \{|t \in \mathbb{Z} : F(t) = 0\} \), is

\[
\lim_{m \to \infty} \lim_{n \to \infty} \sum_i I_{i,0}^{m,n}.
\]

Because \( Z_0 \) is distributed according to Haar measure on \( \mathbb{Z}_p \), the distribution of \( z + F \) is the same for all \( z \in \mathbb{Z}_p \) and so the expectation in question is also the expectation of

\[
\lim_{m \to \infty} \lim_{n \to \infty} p^{-n} \sum_i \sum_j I_{i,j}^{m,n}.
\]

As we observe in Section 3, \( F \) is a stationary process on \( \mathbb{Z}_p \) (this is not at all obvious and will hold if and only if \( |a_0| \geq |a_1| \geq \ldots \) hence our assumption to this effect). Consequently the expectation in question is also the expectation of

\[
\lim_{m \to \infty} \lim_{n \to \infty} p^m p^{-n} \sum_i I_{0,j}^{m,n}.
\]

As in the real case, polynomials look approximately like affine functions on small scales, so for large \( m \) the restriction of \( F \) to the ball \( B_{m,0} \) of radius \( p^{-m} \) around 0 is equivalent up to first order to a random affine function \( t \mapsto Z_0 + b W t \) where \( W \) is standard \( \mathbb{Q}_p \)-Gaussian and \( b \in \mathbb{Q}_p \) is a non-zero constant. This implies first of all that for large \( m \) the restriction is injective, so that \( \lim_{n \to \infty} p^{-n} \sum_i I_{0,j}^{m,n} \) is the Haar measure of the image of \( B_{m,0} \) by \( F \). Moreover, the image has Haar measure approximately that of the image by \( t \mapsto Z_0 + b W t \), which is exactly \( |b||W|p^{-m} \). Thus the expectation in question is nothing other than the expectation of \( |b||W| \). It remains to note that \( |W| \) takes the value \( p^{-r} \) with probability \( p^{-r} - p^{-(r+1)} \) for \( r = 0, 1, 2, \ldots \) to conclude that the expectation of \( |b||W| \) is \( |b| \sum_r (1 - p^{-1}) p^{-2r} = |b|(1 + p^{-1}) \).

Essentially the same heuristic argument works for general \( d \). Once again the problem is reduced to considering the expected Haar measure of the image of a small ball by a random affine function. Computing the actual value of the expectation is more complicated however, as it involves evaluating the expected value of the determinant of the linear part of the affine function.

This paper appears to be the first to consider roots of random polynomials over the \( p \)-adic field. There has been some work on random polynomials over finite fields, see \[ \text{Odo92} \, \text{ABT93} \, \text{IM96} \, \text{Pan04} \, \text{DP04} \].

2 Preliminaries

Write \( \lambda_d \) for the \( d \)-fold product measure \( \lambda \otimes^d \). Thus \( \lambda_d \) is Haar measure on the additive group of \( \mathbb{Q}_p^d \) normalized so that \( \lambda_d(\mathbb{Z}_p^d) = 1 \). The Euclidean analogue of the following result is well-known.

**Lemma 2.1.** For a Borel set \( A \subseteq \mathbb{Q}_p^d \) and a \( d \times d \) matrix \( H \), the set \( H(A) \) has Haar measure \( \lambda_d(H(A)) = |\det(H)| \lambda_d(A) \).
Proof. If $H$ is singular, then the range of $H$ is a lower dimensional subspace of $\mathbb{Q}_p^d$ and the result is obvious.
Suppose then that $H$ is invertible. Write $GL(d, \mathbb{Z}_p)$ for the space of $d \times d$ matrices that have entries in $\mathbb{Z}_p$ and are invertible with the inverse also having entries in $\mathbb{Z}_p$. By Cramer’s rule, a matrix $W$ is in $GL(d, \mathbb{Z}_p)$ if and only if it has entries in $\mathbb{Z}_p$ and $|\det(W)| = 1$. Moreover, $GL(d, \mathbb{Z}_p)$ is the set of linear isometries of $\mathbb{Q}_p^d$ equipped with the metric derived from the norm $|(x_1, x_2, \ldots, x_d)| = \sqrt{\prod_{i=1}^d |x_i|}$ (see Section 3 of [Eva02]). From the representation of $H$ in terms of its elementary divisors, we have

$$H = U \text{diag}(p^{k_1}, p^{k_2}, \ldots, p^{k_d}) V,$$

for integers $k_1, \ldots, k_d$ and matrices $U, V \in GL(d, \mathbb{Z}_p)$ (see Theorem 3.1 of [Eva02]). Because $|\det(U)| = |\det(V)| = 1$, it follows that $|\det(H)| = p^{-(k_1+\cdots+k_d)}$.
From the uniqueness of Haar measure, $\lambda_d \circ U$ and $\lambda_d \circ V$ are both constant multiples of $\lambda_d$.
Both $U$ and $V$ map the ball $\mathbb{Q}_p^d$ bijectively onto itself. Thus $\lambda_d \circ U = \lambda_d \circ V = \lambda_d$.
Again from the uniqueness of Haar measure, $\lambda_d \circ \text{diag}(p^{k_1}, p^{k_2}, \ldots, p^{k_d})$ is a constant multiple of $\lambda_d$. Now

$$\lambda_d \circ \text{diag}(p^{k_1}, p^{k_2}, \ldots, p^{k_d})(\mathbb{Z}_p^d) = \lambda_d \left( \prod_{j=1}^d p^{k_j} \mathbb{Z}_p \right)$$

$$= \prod_{j=1}^d \lambda(p^{k_j} \mathbb{Z}_p) = p^{-(k_1+\cdots+k_d)}$$

$$= |\det(H)| = |\det(H)| \lambda_d(\mathbb{Z}_p^d).$$

Write $gl(d, \mathbb{Q}_p)$ for the space of $d \times d$ matrices with entries in $\mathbb{Q}_p$. We say that a function $f$ from an open subset $X$ of $\mathbb{Q}_p^d$ into $\mathbb{Q}_p^d$ is continuously differentiable if there exists a continuous function $R : X \times X \to gl(d, \mathbb{Q}_p)$ such that $f(x) - f(y) = R(x,y)(x - y)$. This definition is a natural generalization of Definition 27.1 of [Sch84] for the case $d = 1$. Set $Jf(x) = R(x,x)$.
The next result is along the lines of the Euclidean implicit function theorem. It follows from Lemma 2.1 and arguments similar to those which establish the analogous results for $d = 1$ in Proposition 27.3, Lemma 27.4, and Theorem 27.5 of [Sch84].

Lemma 2.2. Suppose for some open subset $X$ of $\mathbb{Q}_p^d$ that $f : X \to \mathbb{Q}_p^d$ is continuously differentiable.

(i) If $Jf(x_0)$ is invertible for some $x_0 \in X$, then, for all sufficiently small balls $B$ containing $x_0$, the function $f$ restricted to $B$ is a bijection onto its image, $f(B) = Jf(x_0)(B)$, and $|\det(Jf(x))| = |\det(Jf(x_0))|$ for $x \in B$. In particular,

$$\lambda_d(f(B)) = |\det(Jf(x_0))| \lambda_d(B).$$

(ii) If $Jf(x_0)$ is singular for some $x_0 \in X$, then, for all sufficiently small balls $B$ containing $x_0$, $\lambda_d(f(B)) = o(\lambda_d(B))$.
The following result is an analogue of a particular instance of Federer's co-area formula. The special case of this result for $d = 1$ and an injective function is the substitution formula in Appendix A.7 of [Sch84].
**Proposition 2.3.** Suppose for some open subset $X$ of $\mathbb{Q}_p^d$ that $f : X \to \mathbb{Q}_p^d$ is continuously differentiable. Then, for any non-negative Borel function $g : \mathbb{Q}_p^d \to \mathbb{R}$,

$$
\int_X g \circ f(x) \left| \det(Jf(x)) \right| \lambda_d(dx) = \int_{\mathbb{Q}_p^d} g(y) \# f^{-1}(y) \lambda_d(dy).
$$

**Proof.** It suffices to consider the case when $g$ is the indicator function of a ball $C$. Write $\delta$ for the diameter of $C$. Put

$$
S := \{ x \in X : Jf(x) \text{ is singular} \}
$$

and

$$
I := \{ x \in X : Jf(x) \text{ is invertible} \}.
$$

From Lemma 2.2(ii), $\lambda_d(f(S)) = 0$, so that

$$
\lambda_d(\{ y \in \mathbb{Q}_p^d : f^{-1}(y) \cap S \neq \emptyset \}) = 0
$$

and

$$
\int_{\mathbb{Q}_p^d} g(y) \# (f^{-1}(y) \cap S) \lambda_d(dy) = 0
$$

$$
= \int_S g \circ f(x) \left| \det(Jf(x)) \right| \lambda_d(dx).
$$

From Lemma 2.2(iii), we can cover the open set $I$ with a countable collection of balls $B_k$ such that $f$ restricted to $B_k$ is a bijection onto its image, $f(B_k) = Jf(x_0)(B)$ for some $x_0 \in B$, $\left| \det(Jf(x)) \right| = \left| \det(Jf(x_0)) \right|$ for all $x \in B_k$, $\lambda_d(f(B_k)) = \left| \det(Jf(x_0)) \right| \lambda_d(B_k)$, and $\text{diam}(f(B_k)) \leq \delta$, so that $g$ is constant on $f(B_k)$. Hence

$$
\int_{\mathbb{Q}_p^d} g(y) \# (f^{-1}(y) \cap B_k) \lambda_d(dy)
$$

$$
= \int_{f(B_k)} g(y) \lambda_d(dy)
$$

$$
= \int_{B_k} g \circ f(x) \left| \det(Jf(x)) \right| \lambda_d(dx)
$$

Summing over $k$ gives

$$
\int_{\mathbb{Q}_p^d} g(y) \# (f^{-1}(y) \cap I) \lambda_d(dy) = \int_I g \circ f(x) \left| \det(Jf(x)) \right| \lambda_d(dx)
$$

and the result follows. $\square$

3  **Proof of Theorem 1.2**

For $x \in \mathbb{Z}_p^d$, write $N(x)$ for the number of points in the set

$$
\{(t_1, t_2, \ldots, t_d) \in \mathbb{Z}_p^d : F_i(t_1, t_2, \ldots, t_d) = x_i, 1 \leq i \leq d \}. $$
Since $Z_{i,0}-(x_1,x_2,\ldots,x_d)$ has the same distribution as $Z_{i,0}$, it follows that $\mathbb{E}[N(\cdot)]$ is constant. Also, by an extension of the argument for $d=1$ in Theorem 9.3 of [Eva89] (see also Theorem 8.2 of [Eva01b]), the stochastic processes $F_i$ are stationary. Thus, by Proposition 2.3,

$$
\mathbb{E}[N(x)] = \int_{\mathbb{Z}_p^d} \mathbb{E}[N(x)] \lambda_d(dx)
$$

$$
= \mathbb{E} \left[ \int_{\mathbb{Z}_p^d} N(x) \lambda_d(dx) \right]
$$

$$
= \mathbb{E} \left[ \int_{\mathbb{Z}_p^d} |\det(JF(t))| \lambda_d(dt) \right]
$$

$$
= \int_{\mathbb{Z}_p^d} \mathbb{E}[|\det(JF(t))|] \lambda_d(dt)
$$

$$
= \mathbb{E} \left[ \int_{\mathbb{Z}_p^d} |\det(JF(t))| \lambda_d(dt) \right]
$$

Now

$$(JF(0))_{ij} = \sum_h a_{he_j} Z_{i,he_j}(0-1)(0-2)\cdots(0-h+1) = b_j W_{ij},$$

where the $W_{ij}$ are standard $\mathbb{Q}_p$-Gaussian random variables and $b_j \in \mathbb{Q}$ is any constant with

$$
|b_j| = \sqrt{\frac{a_{he_j}}{h}},
$$

and so

$$
\det(JF(0)) = \left( \prod_{j=1}^d b_j \right) \det(W_{ij})_{1 \leq i,j \leq d}.
$$

From Theorem 4.1 in [Eva02], we find, putting

$$
\Pi_k := (1-p^{-1})(1-p^{-2})\cdots(1-p^{-k}),
$$

that

$$
\mathbb{E}[|\det(JF(0))|] = \left( \prod_{j=1}^d |b_j| \right) \sum_{h=0}^{\infty} p^{-h} \mathbb{P}\{|\det(W_{ij})|_{1 \leq i,j \leq d} = p^{-h}\}
$$

$$
= \left( \prod_{j=1}^d |b_j| \right) \sum_{h=0}^{\infty} p^{-2h} \frac{\Pi_d \Pi_{d+h-1}}{\Pi_h \Pi_{d-1}}.
$$

The result then follows from a consequence of the $q$-binomial theorem, see Corollary 10.2.2 of [AAR99].

Remark 3.1. (i) Suppose that $a_{(k_1,\ldots,k_d)} = 1$ if $k_i \leq N$ for all $i$ and is zero otherwise. Then $|b_j|$ is just $p^r$, where $r = \lfloor \log_p N \rfloor$ is the largest power of $p$ that divides some integer $\ell$ with $1 \leq \ell \leq N$. 
(ii) Results about level sets of Euclidean processes are often obtained using the Kac-Rice formula. As shown in [AW05], result like the Kac-Rice formula are a consequence of Federer’s co-area formula (see also [AT06] for an extensive discussion of this topic). It would be possible to derive a \( p \)-adic analogue of the Kac-Rice formula from Proposition 2.3 and use it to prove Theorem 1.2. However, the homogeneity in “space” of \( (F_1, F_2, \ldots, F_d) \) makes this unnecessary.

(iii) Because \( (F_1, F_2, \ldots, F_d) \) is stationary, its level sets are all stationary point processes on \( \mathbb{Z}_p^d \) with intensity the multiple of \( \lambda_d \) given in Theorem 1.2.

(iv) The requirement that the \( F_i \) are identically distributed could be weakened. All we actually use is that the distribution of \( (JF(0))_{ij} \) does not depend on \( i \).

Acknowledgment: We thank two anonymous referees for suggestions that improved the presentation of the paper.

Zeros of $p$-adic polynomials
