How to setup international keyboard in X Window with Xmodmap and XKB

by Juraj Sipos, xvudpapc@savba.sk

How to setup international keyboard in Linux or Unix with Xmodmap and XKB written by (c) Juraj Sipos. The Xmodmap is a file that XFree86 reads in order to give you a keyboard layout. This solution will work for you in setting up any international keyboard for (Debian, RedHat, Mandrake, CorelLinux) Linux, FreeBSD, OpenBSD, NetBSD and possibly every Unix that uses XFree86. The advantage of this howto is that it is not architecture specific and will work on all other systems.

1.3. Introduction

The international keyboard Xmodmap HOWTO. Copyright (C) 1999, 2002 Juraj Sipos (xvudpapc@savba.sk).

Imagine you use a Linux or a BSD OS and want to write a business letter to a person that has a foreign name with a slash or diaeresis (two dots above a letter). Czech language uses signs like o and many European languages have their special non–English characters.

This is the Xmodmap Howto, but some info on XKB is included, too. Why Xmodmap? Xmodmap is a little hackers' solution that lets you gain a complete control of a keyboard – you can map the keyboard to almost everything. You can do this with XKB, too, but it's a little dirtier way, albeit a possible one. A good idea is to keep your XKB maps clean and unmodified, so that you don't have to reinstall your Unix box. Xmodmap solution helps you map keyboard to your choice and if something goes wrong, you will be able to use
How to setup international keyboard in X Window with Xmodmap and XKB

standard X keyboard. Some people also like their own customized keyboard layouts and this HOWTO will explain how to achieve this.

With information in this file you can make your own customized (international) keyboard layouts without installing any additional packages. The following information will help you set up German, Spanish, Italian, Slovak, Czech, Polish, Slovenian, Croatian, Danish, Dutch, French, Finnish, Norwegian, Estonian, Latvian, Swedish and other keyboards. You can also alternatively look at my hompage at http://www.freebsd.nfo.sk to see visual layouts of various keyboards. In case you want to install Greek, Hebrew or Russian language, follow my information and apply changes pertinent to these languages also with respect to other documentation (e.g., install Greek fonts, etc., see the Cyrilic, Hebrew, or Danish howto).
2. Setting up international keyboard in X Window System with Xmodmap and XKB

2.1. Quick start

2.1.1. Xmodmap

Make your own .Xmodmap file according to information in this file.

Write the following to your .bash_profile in your home directory:

```bash
export LANG=language
```

where "language" is the language you want to use. The languages can be found in the file locale.alias in /usr/X11R6/lib/X11/locale. NOTE: some programs, like Mozilla, don't care about these user's locale settings. Run "exit" command on the console and log in again for Bash to read the statement from its .bash_profile.

Install fonts (best are ISO8859−2 Type1 fonts for Eastern Europe, Czech or Slovak), put them in your font path in the /etc/X11/XF86Config file (on some newer systems this is not necessary). Start X Server (startx). If you use GDM or XDM and your X server is already running, restart X server. Run the command "xmodmap /Xmodmap" from the X terminal window to force the system to read the .Xmodmap file. The dot does not have to be there. Name the xmodmap keyboard map whatever way you want. Switch keyboard by pressing a key (it is usually right Alt, Scroll Lock, it depends on how switching is defined in the xmodmap file). That's all. NOTE: This HOWTO is for the X Window System, use of national keyboards on the console is not explained here. If you are desperate, try to issue the commands like:

```bash
setfont LatArCyrHeb−14 −m 8859−2
```

followed by

```bash
loadkeys sk
```

("sk" stands for the Slovak language). Most Linuxes have their own utilities to set up console keyboards).

2.1.2. XKB

Provided you have your fonts installed, just open the X terminal window and issue a command: setxkbmap kb, where "kb" is the keyboard layout you want to use, for example:

```bash
setxkbmap si
```

for the Slovenian language

```bash
setxkbmap de
```

for the German language

All the language names you may use are located in /usr/X11R6/lib/X11/xkb/symbols directory.
How to setup international keyboard in X Window with Xmodmap and XKB

Alternatively, if you are using KDE 2.0, open the KDE Start button, click on Preferences, Personalization, Country & Language and choose ISO8859–2 charset. Note that this may be slightly different depending on the Linux or KDE distribution. In newer Linux distributions you don't have to do this anymore; in Slackware Linux 8.1, RedHat 8.0 or Mandrake 9 with KDE 3.0, for example, just open Preferences, Peripherals, Keyboard – choose your keyboard layout and everything should work fine (if you have the fonts pertinent for the language of your choice installed, obviously).

You will see a language icon on the KDE panel. Switch the keyboard (NOTE: this is for XKB, my xmodmap definition uses Scroll Lock for switching, other xmodmap files use Right Alt) and enjoy.

You may alternatively edit the /etc/X11/Xf86Config file as explained in the Danish Howto, or issue this command in an X terminal window for the Slovak keyboard:

```
setxkbmap -model pc102 -symbols 'czsk(us_sk_qwertz)' setxkbmap cs -option grp:shift_toggle
```

In RedHat 7.2 and Mandrake 8.1, it is enough to run the following setxkbmap command from an X Terminal Window (assuming you have correct fonts installed):

```
setxkbmap sk
setxkbmap si
setxkbmap de
```

qwerty or qwertz means that the letter z Z and y Y are swapped.

To see a variety of language maps (symbols), look in the file symbols.dir in /usr/X11R6/lib/X11/xkb directory.

Some X Window managers override .Xmodmap setting. If .Xmodmap isn't read by X automatically after starting the X Window System, a good way is to force the system to read it from your root (home) directory. You will do this by issuing the following command from an X terminal window:

```
xmodmap ~/.Xmodmap
```

After I installed the Slovak keyboard in KDE with Xmodmap file that used definitions for ISO8859–2 keycode entities (lcaron, scaron, etc.), some changes had to be done in the system in relation to a Linux or XFree distribution. The changes mostly pertained to dead keys that did not work.
3. How to do it: this experimental solution is a legacy issue – do not read it if you use newer systems

Before the year 2000, I used the following way to customize keyboard in X Window System on some Unices. Put the following in your .bash_profile:

`export LANG=language`

OR

OR for csh shell

`setenv LANG=language`

and have the Xmodmap file in your home directory. If you ask me where you may obtain such Xmodmap files, some are in this HOWTO, or go to GNOME ../share directory. The file `/usr/X11R6/lib/X11/locale/locale.alias` contains the aliases for languages, so look there in order to find out what is ca_ES or br_FR (the exact syntax for your language to use – you cannot write "croatia" but you must write "croatian", not "Croatian"; this is very important, as Unix is case sensitive).

Now you must install the pertinent language fonts and put path in XF86Config file to these fonts. If you want to internationalize your keyboard, use the standard Xmodmap definitions first and use right alt to switch between keyboards (if you use GNOME Xmodmap files). If it does not work, do the following:

b) Put the included .Xmodmap file to your root directory (Slovak language, or make your own .Xmodmap file, or choose from the ones listed here).

c) Install ISO8859–2 fonts (or other pertinent fonts).

You may try to issue the command:

`xset q`

to see which fonts are in your path.

If you want to add fonts in your path from the X Window System, issue the command:

`xset fp+ /usr/fonts_path`

`xset fp rehash`

d) Disable every "Scroll Lock" uncommented line in your XF86Config, because our .Xmodmap file for the Slovak language uses the Scroll Lock to switch between keyboards.
e) Put the appropriate fontpath for your newly installed fonts in the XF86Config file, if necessary (Mandrake 7.2 and other OS's may not require this). The Xmodmap solution may be applied to all X keyboards of your choice.

First, I must say that in my solution (in older XFree86 versions), different mapping, if used, appears to work for Xmodmap keycodes for some ISO8859-2 keycode entities. ISO8859-2 definitions (keycode entities) like lcaron, zcaron actually do not work. This means that the ISO8859-1 definitions must be used instead and they will either give you what they say they are (aacute [o?=, eacute [o?=, etc.), or they will not give you what they say they are (using ISO8859-2 fonts, putting "threequarters" in your .Xmodmap file will not give you "3/4" but "z" with a caron, a reversed ^ above it). For example, "mu" will give lcaron, "oslash" rcaron, etc.

However, other key definitions, for example, adieresis (a with two dots above it), uacute (u with a slash above it), as well as dead_diaeresis do not require a substitution of other definitions and work pretty well, as they're defined everywhere (a dead key is a key you press, hold it, yet nothing happens, but after pressing another key you will get a special letter).

The original "Compose" file in ../iso8859-1 directory can be fully utilized for English, Slovak or Czech keyboard layouts (Polish, Hungarian, Slovenian, Croatian) in some older XFree86 distributions, but there is only one problem – dead keys do not work. That's why you have to copy the "Compose" file from the iso8859-2 directory to iso8859-1 directory, or alternatively, you can edit the "Compose" file in iso8859-1 directory.

You can leave the Keyboard section in your XF86Config file without much change. Put (if it's not already there) the following in the "Keyboard" section:

```
Section "Keyboard"
Protocol "Standard"
XkbRules "xfree86"
XkbModel "pc101"
XkbLayout "us"
```

Force the system to read the xmodmap map by issuing the command: "xmodmap /.Xmodmap". Alternatively, you can have 60 .Xmodmap files like .Xmo1, .Xmo2, .Xmo3, .Xmo4, etc., and you may force the system to read them (xmodmap /.Xmo1). The dot means it is a hidden file and it is not necessary. You may also have xmo1, xmo2, or xmo3 Xmodmap files.

NOTE: If you are using some legacy programs like StarOffice 5.2, they have their own fonts, so Xmodmap solution will not work on older systems immediately with these applications. StarOffice 6.0 handles well conversion to win1250 and vice versa, so you can transport documents to a M$ platform. In my Mandrake 8.0, StarOffice 6.0 was internationalized immediately after using my standard Xmodmap solution. All the fonts worked. However, with StarOffice 5.2 this is not the case. In StarOffice 5.2, you must add X fonts to StarOffice's fonts directory. Here is a script that will do it for you. Cut it, name it "so52", make it executable (chmod +x so52), copy it to the StarOffice5.2/share/xp3 directory and execute it there.

```
#!/bin/sh

#!/bin/sh
3. How to do it: this experimental solution is a legacy issue – do not read it if you use newer system
```
How to setup international keyboard in X Window with Xmodmap and XKB

# Put path to your StarOffice here

STAR_OFFICE_ROOT=/mnt/StarOffice5.2

# ------------------------------------------------------------------------

# Don't edit the script here

# ------------------------------------------------------------------------

XP3_DIR=$STAR_OFFICE_ROOT/share/xp3

if [ -e $XP3_DIR/psstd.fonts.il2 ]; then
    echo "Changes were already done!"
    echo "If there's a problem, delete the file"
    echo "$XP3_DIR/psstd.fonts.il2"
    exit 1
fi

if [ -e $FONTS_DIR/afm ]; then
    AFM_DIR=$FONTS_DIR/afm
else
    AFM_DIR=$FONTS_DIR
fi

# Link AFM files.

ln -sf $AFM_DIR/*.[aA][fF][mM] $XP3_DIR/fontmetrics/afm

# Link PFB files.

ln -sf $FONTS_DIR/*.[pP][fF][bB] $XP3_DIR/pssoftfonts

grep "\.pf" $FONTS_DIR/fonts.dir \ | sed -e 's/\n/ /g' -e 's/-0-0-0-0-/-%d-%d-%d-%d-//g' \  > $XP3_DIR/psstd.fonts.il2

cat $XP3_DIR/psstd.fonts.il2 >> $XP3_DIR/psstd.fonts

3. How to do it: this experimental solution is a legacy issue – do not read it if you use newer system
StarOffice 5.2 fully recognizes Word97 documents even written in other languages, but a converter from iso8859–2 to win1250 encoding is necessary in order to transport ISO8859–2 documents to M$ platform. For html documents this is not necessary.

StarOffice 5.2 can be thus used by professional translators.

### 3.1. Xmodmap theory and Xmodmap solution

If you want to edit and make your own .Xmodmap keyboard layout definitions, I'll explain one line of the .Xmodmap file to make clear what you should do.

This example can be used for all keycodes. For example, the line:

```
keycode 0x11 = 8 asterisk aacute 8
```

(note: keycode 0x11 is derived from the "xkeycaps" utility; you can also use the X Window "xev" utility to explore keyboard puzzles.)

says that the first pair, the default one, (number "8" and "asterisk") will display number "8" when you press keycode 0x11 ("8"), will display asterisk when a "shift" key is pressed. After pressing the Scroll Lock, there's another definition: ISO_NEXT_GROUP, which means that when you press the default "8" key, no "8" will be displayed, but aacute (á); when you press the "shift" key, number "8" will be displayed. So if you change "aacute" and "8", anything you put instead of "aacute" and "8" will be displayed, for example:

```
keycode 0x11 = 8 asterisk semicolon colon
```

will give you "semicolon" and "colon" in your 0x11 keycode after pressing the Scroll Lock.

The ISO_NEXT_GROUP is defined by another line. If this line is not defined, you will be able to use only two definitions ("8" and "asterisk") - look at my .Xmodmap file. If you delete the ISO_NEXT_GROUP (the next pair of definitions on the right), you will have only one group of keyboard definitions ("8" and "asterisk"). Be careful when editing the .Xmodmap file. You mustn't delete definitions that enable utilization of the Scroll Lock unless you know what you are doing (or you map the second keyboard by right Alt). These are the lines such as:

```
keycode 0x4e = ISO_Next_Group

add mod5 = ISO_Next_Group,
```

etc. You must also keep in mind that Unices are case sensitive. If you want to find out more about keycodes, install the package "xkeycaps" or use "xev".

The following symbols on your right is what I found out through my research. This is just an example. When you use a "Pound" definition in the Xmodmap file, the X Window System will display you a Lslash instead (in relation to using iso8859–2 fonts, of course). When you choose some easy KDE text editor, select iso8859–2 fonts charset from the fonts menu. NOTE: vowel *acute (uacute, eacute, etc.) signs require no substitution, therefore I omitted iacute, aacute, etc., here.

3. How to do it: this experimental solution is a legacy issue – do not read it if you use newer systems.

cut_here

You may find almost any xmodmap file in the GNOME directory in (SuSE) /opt/gnome/share/xmodmap (with standard ISO8859-1.2 and other definitions). To switch between the keyboards, use right Alt.

3. How to do it: this experimental solution is a legacy issue – do not read it if you use newer systems.
4. Xmodmap theory and Xmodmap solution

If you want to edit and make your own .Xmodmap keyboard layout definitions, I'll explain one line of the .Xmodmap file to make clear what you should do.

This explanation can be used for all keycodes. For example, the line:

```
keycode 0x11 = 8 asterisk aacute 8
```

(note: keycode 0x11 is derived from the "xkeycaps" utility; you can also use the X Window "xev" utility to explore keyboard puzzles.)

says that the first pair, the default one, (number "8" and "asterisk") will display number "8" when you press keycode 0x11 ("8"), will display asterisk when a "shift" key is pressed. After pressing the Scroll Lock, there's another definition: ISO_NEXT_GROUP, which means that when you press the default "8" key, no "8" will be displayed, but aacute (á); when you press the "shift" key, number "8" will be displayed. So if you change "aacute" and "8", anything you put instead of "aacute" and "8" will be displayed, for example:

```
keycode 0x11 = 8 asterisk semicolon colon
```

will give you "semicolon" and "colon" in your 0x11 keycode after pressing the Scroll Lock.

The ISO_NEXT_GROUP is defined by another line. If this line is not defined, you will be able to use only two definitions ("8" and "asterisk") − look at my .Xmodmap file. If you delete the ISO_NEXT_GROUP (the next pair of definitions on the right), you will have only one group of keyboard definitions ("8" and "asterisk"). Be careful when editing the .Xmodmap file. You mustn't delete definitions that enable utilization of the Scroll Lock unless you know what you are doing (or you map the second keyboard by right Alt). These are the lines such as:

```
keycode 0x4e = ISO_Next_Group
```

add mod5 = ISO_Next_Group,

etc. You must also keep in mind that Unixes are case sensitive. If you want to find out more about keycodes, install the package "xkeycaps" or use "xev".

4.1. .Xmodmap sample file for the Slovak language typewriter layout

The following .Xmodmap sample file consists of two groups of keyboard definitions you may use in addition to your default or XKB keyboard choice. You may use this file as an example to build your own keyboard maps. This file needs editing for your specific purposes and it's here only as a hint. If you change letters like "y Y" to "t T", you will have "t T", etc. on your keyboard where you normally have "y Y" keys. So you see that thus you can have almost absolute control of your keyboard − something which in Microsoft Windows operating system can only be achieved by special and certainly expensive programs. Use the Scroll Lock to switch between the first and second group of key definitions.

```
keycode 0x09 = Escape
```

5. Character sets

If you want to build an .Xmodmap and you know how the character looks visually, you may have problems about knowing how it is defined by name. A good site that may help you with this may be: http://www.geocities.com/gorazd.hribar/latin–2/eng–iso–8859–2.html Here you can see ISO8859–2 characters visually.

I also included here some ISO8859–2 Character definitions for you to know which names are used for pertinent keys. It may not be complete and you should not bother about the keycode numbers, but notice how keys are named. Much of this information is useful to build a keyboard with ISO8859–1 characters only, or a combination of East European characters and Western characters. If you're going to use other languages than the Central European or West–European ones, find a pertinent table for your ISO*** character set on the Internet. The gdkkeysyms.h file that contains all the crazy names for keycode entities including hexcodes is in (older versions of RedHat) /usr/include/gdk/ directory. If no gdkkeysyms.h file is on your system, see the file /usr/X11R6/include/X11/keysymdef.h (you must install XFree86 development package to make use of this directory), or try to look in /lib/perl5/site_perl/5.6.0/i386–linux/GTK/keysyms.pm (it also contains names of keycode entities including hex codes). If you have a newer version of PERL, the version number "5.6.0" may differ. The similar thing should apply to other systems (FreeBSD), too, as they also use PERL.

5.1. ISO–8859–2 (ISO Latin2) character set

Xmodmap entities with their word definitions (which you put in the Xmodmap file) and their visual representation. Some word definitions lack their visual forms.

5. Character sets
First, if you are using older systems (see the legacy solution), try to see if definitions will give you (after installing pertinent fonts and building the Xmodmap map with keyboard definitions for X) what they say they are. If they will not give you what they say they are, see my legacy solution.

5. Character sets
5. Character sets
6. How this Xmodmap solution works on various systems

6.1. SuSE 6.4 and 7.0

6.1.1. SuSE 7.0 with XFree86 version 3.3.6 and KDE 2.0 (this also applies to SuSE 6.4)

No LANG=language statement is necessary in your bash_profile. You may use the Xmodmap file with standard ISO8859−2 keycode definitions and the .Xmodmap file (not from the legacy solution).

Unfortunately, although you may immediately start writing with ISO8859−2 keycodes, the dead keys are not working properly and export LANG=language does not work here in order to make these dead keys work. There's also some bug with fonts or something − KDE 2.0 (or older XFree86 does not properly handle ISO8859−2 fonts together with Xmodmap. Old kedit, newest GNOME's gedit and StarOffice 5.2 work well (after applying the above script for StarOffice 5.2).

After copying the Compose file from /usr/X11R6/lib/X11/locale/iso8859−2/ to the /usr/X11R6/lib/X11/locale/iso8859−1/, you may start elegantly working with dead keys. This was also tested on StarOffice 5.2.

6.2. SuSE 7.0 (Xfree86 3.3.6, KDE 1.x), SuSE 8.0

SuSE 7.0 works same as above. SuSE 8.0 works without problems − just apply the xmodmap command on your xmodmap keyboard definition and you are ready to go. It is a good idea to install support for your national language in Yast2, if there is a problem.

6.3. Mandrake Linux 7.2

6.3.1. Mandrake Linux 7.2 – works as it should

Yes, it works as it should − I used the "kcmshell Personalization/kcmlayout", command, which is in the menu in Configuration > KDE > Personalization > keyboard layout and after just putting the LANG=language statement in my .bash_profile, StarOffice worked immediately (with ISO8859−2 fonts added to its directory) and I only switched the keyboards. I chose Czechoslovakian as the second language and could write in Czech with ISO8859−2 characters on my screen. (I used the script for putting the ISO8859−2 fonts for StarOffice).

Unfortunately, the KDE 2.0 kedit could not visualize the ISO8859−2 fonts and after switching the keyboard and selecting ISO8859−2 charset I saw this: ??????? instead of lcaron, scaron, etc., but *acute symbols (uacute, aacute, etc.) displayed well.

The maps in /usr/X11R6/lib/X11/xkb/symbols can be modified on the fly, but this is a dirtier way than to modify Xmodmap maps. You switch keyboards from the panel flag icon.
6.3.2. Mandrake Linux 7.2 with XFree86 version 3.3.6

Apply the standard .Xmodmap keycodes (scaron, lcaron, not "threequarters" or "mu", etc.) and issue the command: "xmodmap ~/.Xmodmap" and you may work by switching the keyboards by pressing Scroll Lock (if you use my Xmodmap file; if you use other Xmodmap file, try right Alt or whatever else that is defined in the Xmodmap file).

The FontPath statement in /etc/X11/XF86Config and /etc/X11/XF86Config does not have to be changed:

FontPath "unix:/1"

The XFree86 reads automatically your fonts, but I put the ISO8859−2 fonts to /usr/share/fonts directory (same as in RedHat). Surprisingly, you do not have to copy the ..ISO8859−2/Compose file to ..ISO8859−1 directory and dead keys work nicely.

6.4. Mandrake 8.1

These distributions work well as they should. In KDE, you must open the menu: Start > Preferences > Personalization > Country and Language, where you will change CHARSET from ISO8859−1 to ISO8859−2 (or ISO8859−X for any other language of your choice). Then you may either select a keyboard layout – Peripherals, Keyboard (Slovak is included with dozens of other keyboard XKB maps) from the menu: Start > Configuration > KDE > Personalisation > Peripherals > Keyboard, or you may choose my Standard Xmodmap solution. No other files require editing. That's great! Alternatively, you can set your keyboard with setxkbmap command (see section FreeBSD 4.4).

6.5. RedHat 5.1, 5.2, 6.0, 6.1 and 6.2 (XFree86 3.3.6 and older)

The legacy solution must be used here. No LANG=language statement is necessary in your bash_profile. Here the "experimental" .Xmodmap solution works ("mu" instead of "lcaron", etc.) and you must copy the Compose file from ..ISO8859−2 to ISO8859−1 directory in order for dead keys to work. There is only one XF86Config file in /etc/X11 and its FontPath must contain path to the pertinent fonts.

6.6. RedHat 7.2, RedHat 8.0, Slackware 8.1

RedHat 7.2 behaves same as Mandrake 8.1. RedHat 8.0, with KDE 3, works nicely without problems – you can use the xmodmap solution immediately without digging up in the system and changing configurations. You do not have to go to Look and Feel menu in the Preferences menu – you can either apply the xmodmap solution immediately, or you can choose to configure (add) keyboard in the Preferences – Peripherals menu (if you decide for XKB). You will have the keyboard icon placed on the panel and you just click on it to switch between keyboards. Slackware 8.1 behaves exactly as RedHat 8.0, I only had to include the "export= language command (both for XKB and Xmodmap solution) in the Bash profile for the dead keys to work.

6.7. FreeBSD 3.1 and 3.2

Internationalization works the same way as with RedHat 5.1, 5.2, 6.0, 6.1, 6.2
6.8. FreeBSD 4.1, 4.2, 4.3, 4.4, 4.5

No LANG=language statement is necessary in your bash_profile. But you must put this to /etc/profile:
LANG=cs_CZ.ISO_8859−2; export LANG

FreeBSD 4.1, 4.2, 4.3, 4.4 does not use Slovak locale, so we must use the Czech one here. It really does not
matter. Here this depends on XFree86. Because the FreeBSD guys are too conservative about newer versions,
they ship FreeBSD with older versions of XFree86. In FreeBSD 4.1 the experimental .Xmodmap solution
works and you have to copy the ../ISO8859−2/Compose file to ../ISO8859−1 directory to make the dead keys
work.

The Standard Xmodmap solution works well. I think this version has some problems with installation – after
installing the system, I missed some things I had selected in the installation wizard. A good idea would be to
upgrade.

If you decide to run setxkbmap (FreeBSD or Linux), you may use

setxkbmap si

as a command from an X Terminal for the Slovenian language

setxkbmap se

for Swedish

setxkbmap de

for German, etc.

A brief overview of names that stand for XKB maps:

am Armenian keyboard
be Belgian
de German
can Canadian
cs Czech
dk Danish
es Spanish
fi Finnish
6.10. Corel Linux 1.0 and 1.1

Same as with FreeBSD 3.x – legacy Xmodmap solution must be applied.
7. ISO* specifications

ISO8859–1 Western Europe: Danish, Dutch, English, Faeroese, Finnish, Flemish, French, German, Icelandic, Irish, Italian, Norwegian, Portuguese, Spanish, and Swedish. Many other languages can be written with this.

ISO8859–2 Eastern Europe: Czech, Slovak, English, German, Hungarian, Polish, Romanian, Serbo–Croatian, Slovak, Slovene.

ISO8859–3 English, Esperanto, Galician, Maltese and Turkish.

ISO8859–5 Latin/Cyrillic alphabet: Bulgarian, Byelorussian, English, Macedonian, Russian, Serbian, Ukrainian.

ISO8859–6 Latin/Arabic alphabet: English, Arabic.

ISO8859–7 Latin/Greek alphabet: English, Greek.

ISO8859–9 Latin alphabet: Danish, Dutch, English, Finnish, French, German, Irish, Italian, Norwegian, Portuguese, Spanish, Swedish, Turkish, formed by extending ISO8859–1.

ISO8859–10 Latin alphabet: Modification of ISO8859–4

ISO8859–11 Latin/Thai alphabet.

ISO8859–12 Reserved.

ISO8859–13 Baltic.

ISO8859–14 Celtic

ISO8859–15 Similar to Latin–1

ISO8859–16 Albanian, Croatian, English, Finnish, French, German, Hungarian, Irish Gaelic, Italian, Latin, Polish, Romanian, Slovenian, Lithuanian, and Scandinavian languages (Danish, Faeroese, Icelandic.
8. Some national Xmodmap files

Please note: I am not the author of these files and don't mail me if you find something incorrect in them. These files were taken from the GNOME distribution and the main focus of this howto is to tell you how to map various keycode entities. Use right Alt to switch the keyboard.

! in "windows" keyboards the postion of the key is annoying, is where AltGr
! usually resides, so go define it as AltGr
keycode 116 = Mode_switch

! right windows−menu key keycode 117 = Multi_key

8. Some national Xmodmap files
How to setup international keyboard in X Window with Xmodmap and XKB

clear Shift
clear Lock
clear Control
clear Mod1
clear Mod2
clear Mod3
clear Mod4
clear Mod5
add Shift = Shift_L Shift_R
add Lock = Caps_Lock
add Control = Control_L Control_R
add Mod1 = Alt_L
!Mode_switch add Mod2 = Mode_switch
9. Troubleshooting and some Xmodmap tips

9.1. Troubleshooting

Get the newest Linux distribution. Mandrake 8.1 or RedHat 7.2 or 8.0 work fantastically with regard to internationalization (which could not be said about previous distributions). If locales are not installed, you must install them. The GNU C Library comes with a locale database, which you should have on your system. Upgrade your glibc. Troubleshooting of older versions of XFree or KDE is insignificant in my opinion, as the systems get better and better and people install newer versions. You may find almost any xmodmap file in the GNOME directory in (SuSE) /opt/gnome/share/xmodmap (with standard ISO8859−1,2 and other definitions). To switch between the keyboards, use right Alt. Slackware has a very good database of xmodmap maps in /usr/share/xmodmap. Use the command: locale −a to see all the locales.

9.2. Tips

If you want to list the current keymap table, issue the command: xmodmap −pk | more

The xkeycaps program is a sort of graphical front−end for xmodmap. Start it and see which numbers mean which keycode.

To make the mouse buttons left−handed, use a command: xmodmap −e "pointer = 3 2 1"

To remove the CapsLock and change it to a control key, write this in your Xmodmap file:

remove Lock = Caps_Lock keysym Caps_Lock = Control_L add Control = Control_L
